GEOLOGICAL COMMENTS

BIOSTRATIGRAPHY

INTERPRETATIVE DATA

BASIC DATA

SPECIES CHECK LIST

INTRODUCTION

Three conventional core and two cuttings samples, representing the interval 910-7776.0ft. in Hindhaugh Creek-1 were processed and analysed for spore-pollen and dinoflagellates.

Yields were adequate to good although preservation was mostly poor due to thermal alteration and fragmentation. As with other carbonized palynofloras of Early Cretaceous age in the Torquay Sub-basin, it is possible that the more delicate zone index species have not been preserved and, consequently, most age-determinations and zone boundary picks are of low confidence.

Lithological units and palynological determinations are summarized below. Interpretative and basic data are given in Tables 1 and 2 respectively. Check lists of all species recorded are attached.

SUMMARY

AGE	UNIT*	ZONÉ	DEPTH RANGE (ft.)	ENVIRONMENT
Lower Albian	EUMERELLA FORMATION	C. striatus	910 - 1257.0	Fluvio-lacustrine
Aptian	u	C. hughesii	3665.5- 7776.0	11

Mid Eum -Heathfield Lower Eums - Windermer M.

TD 2372m

* Lithological and electric log data not available

GEOLOGICAL COMMENTS

- 1. Despite the high degree of thermal alteration, palynomorphs are preserved in the Hindhaugh Creek-1 core samples. The negligible or zero recovery reported in previous analyses (Douglas/Burger) is likely to reflect poor processing techniques.
- TAI values range from estimated 3+ [mature] at 910-20ft. to 5 [dry gas] at 7340-7776.0ft.
- 3. Based on the palynofloras recovered in this review, the interval 910-7776ft. is Eumeralla Formation. It is probable that the well bottomed [TD 7782ft.] in this unit of the Otway Group.

BIOSTRATIGRAPHY

Zone and age-determinations have been made using criteria proposed by Helby <u>et al</u>. (1987), augmented where necessary by time-range data presented in Dettman (1963), Burger (1980), Morgan (1980) and Backhouse (1988).

In spite of carbonization and fragmentation of the palynomorphs, sufficient fine sculptural detail was preserved to allow reliable identification of most spore-pollen. Nevertheless it is possible that the more delicate types, including the zone index species <u>Crybelosporites</u> striatus, may not have been preserved.

Cyclosporites hughesii Zone 3665.5-7776.0ft.

Aptian

Three samples are provisionally assigned to this zone, based on fragmented specimens of the nominate species in Core 3 [7776.0ft.] and cuttings from 7340-50ft. The uppermost sample, Core 2 [3665.5ft.] lacks <u>Cyclosporites hughesii</u> but is unlikely to be older than <u>C. hughesii</u> Zone given the occurrence of a poorly-preserved (probable) specimen of <u>Pilosisporites notensis</u>. <u>Crybelosporites striatus</u> was not recorded.

Crybelosporites striatus Zone 910-1257.0ft.

Lower Albian

Two samples are provisionally assigned to this zone, based on a fragmented (probable) specimen of the nominate species in Core 1 [1257.0ft.]. <u>Pilosisporites notensis</u> indicates that the cuttings at 910-20ft. are no older than <u>C. hughesii</u> Zone.
