REPORT ON THE MID WEST NO.2 BORE, LAKES ENTRANCE, EAST GIPPSLAND.

### LOCATION .-

This bore is situated 144 chains to the N.E. of the Government Bore No.1 (3) the Bridge, Lakes Entrance.

### DATE OF DRILLING .-

The original log prepared by Mr.Lightner states that it was spudded on 18/6/31.

### DRILLING METHODS .-

The percussion or Churn Drilling equipment was used in this bore. Bore material so obtained is not entirely from satisfactory from the point of view of making a thoroughly detailed scientific examination.

The following results must therefore be taken with a certain amount of caution. However, from the fact that casing was used to line the bore-hole down to 2656 feet, leaving only 744 feet uncased down to 3400 feet, has reduced the chances of the samples being greatly mixed. Indeed, from this examination data have been checked up which go to prove that they are perhaps more reliable than could have been expected by such methods.

It is a matter of regret that during boring operations a stricter method of procuring samples was not carried dut and a more complete sequence preserved. The material available, however, has supplied some very interesting, not to say unexpected geo palaeographic data, which throws much light on the early topography of the district.

Although there was no marked carelessness in collecting the samples, as seen in the remarkable consistence of the occurrence of the little organisms in the Lower Oligocene sands, there was one example of wrong allocation, where, at a reputed depth of 1250' a reddish granitic sand with quartz and chlorite is intercalated in the Glauconite series. This seems to have come from about 200 feet lower in the series. The percussion method of drilling accounts for the comminuted character of the samples throughout. By the percussion drill it would have been impossible to bore through in the time a solid mass of granite, hence it is logical to regard the granitic sands as such, and, supported by the occurrence of the granitic solid organisms, to refer them to the Lower Oligocene as an accumulation of sediments of exceptional thickness. The The granite rubble which was encountered at intervals in the bore may be regarded as a gravel sheet derived from adjacent granite outcrops.

### DEPTHS OF SAMPLES, WITH BREAKS INDICATED.

Surface to 1100 feet. No samples preserved. 1100 feet to 1259 feet 6 inches, at reasonable intervals, then gap to 1466 feet.

1466 feet to 2590 feet, at fairly reasonable intervals, then gap to 3203 feet, last sample available.

The driller's Log reports the bore to have reached 3400 feet, "in grey shale interbedded with felsitic bands". Until samples from these lower depths are forthcoming it is impossible to say what these lowest samples indicate.

### PROBABLE AGES OF THE BEDS PASSED THROUGH.

No samples were apparently preserved down to the base of the Lower Miocene. From 1100 feet down to 1227 feet, at which depth "Oil Sands" were struck according to Lightner's log, the beds belong to the higher part of the Upper Oligocene, namely the Micaceous Shales of Zone  $A_2$ . An ample and typical foraminiferal fauna proves this. The fossil oysters met with at 1234 feet, O<u>strea</u> cf. <u>hyotidoidea</u>, range in other parts **o**f Victoria from Upper Oligocene to Lower Miocene.

From 1227 feet to 1259 feet 6 inches the lower part of the Upper Oligocene is evident, namely the Glauconitic Series of Zone  $A_2$ , showing a thickness of 32 feet 6 inches.

From 1259 feet 6 inches there is a gap in the samples

available, the next being from 1466 to 2590 feet, or a thickness of 1124 feet, and to these beds I would ascribe a Lower Oligocene age(Zone  $A_1$ ). These granitic sands are undoubtedly of sedimentary origin as they contain a distinct arenaceous foraminiferal faunula. There is nothing leading one to suppose these terrigenous sands are of earlier age than Oligocene, excepting in perhaps the occurrence of cf. <u>Agathammina</u> which elsewhere denotes a Carboniferous to Permian age, but as these are doubtful they carry no weight.

The remainder of the foraminiferal genera present are found equally distributed through the Tertiary terrigenous deposits in many parts of the world, as well as in Recent marine muds from the North Atlantic to the Antarctic.

From 2590 feet to 3203 feet there is a gap in the samples available; at the latter depth the sample here examined is represented by granite rubble.

### SIGNIFICANCE OF THE MID-WEST.NO.2 BORE.

This bore is of exceptional interest amongst the many put down in the Lakes Entrance area, since it reached the great depth of 3400 feet (See note on Depths of Samples, supra cit.).

Until this examination in detail of all the samples available from Mid West 2 was carried out, the only geological note on the bore was based on a single sample from 1810 feet to 1815 feet. It was written by the author of this report whilst Commonwealth Palaeontologist and sent to Canberra and to the Victorian Mines Department on 5/8/32. The note is as follows:-

"This material is in the nature of a fine greenish brown granitic sand. The washed material shows it to be detrital granite. The greenish colour is probably due to the accidental introduction of a certain amount of glauconite and limonitic sludge".

No sample from the above depth(1810 feet to 1815 feet) was available to me in this present series, but at 1780 feet the characters are very similar.

From my original description of the sample mentioned, as "granitic sand", it was apparently inferred by the Mines

3

Department that granite had been reached. It is now shown that from 1466 feet, and probably much higher(1302 feet in Lightner's log, where he records "white sand") the series most likely belongs to the Lower Oligocene series. It is of sedimentary origin, that is often laid down under shallow marine conditions, though terrigenous or land-derived. Most of the samples from 1466 feet to 2590 feet contain foraminifera, usually very minute and with tests formed of fine sand grains. These foraminifera belong to genera usually characterising, though not exclusively, estuarine deposits, such as <u>Psammonyx</u>, <u>Trochamminoides</u>, <u>Haplophragmoides</u>, <u>Ammomarginulina</u>, <u>Ammobaculites</u>, <u>Discammina</u>, <u>Placopsilina</u>, <u>Spiroplectammina</u>, <u>Trochammina</u>.

The granitic sands themselves have been clearly derived from igneous rocks related to, or even identical with, the granodiorites and gneisses such as are found now exposed at Mt.Leinster and in the Benambra Highlands, the former about 72 miles due north of the East Gippsland(Lakes Entrance) region(see E.Broadhurst and J.D.Campbell, Proc.Roy.Soc.Vict.1933,vol.XLV. pt.II."The Geology and Petrology of the Mt.Leinster District, N.E. Victoria", pp.219-240,pl.X.)

As early as 1903, the late Prof.J.W.Gregory referred to the granites(granodiorite) of northern Benambra as part of the primitive mountain chain of Victoria(Geography of Victoria,p.75) and further that""the Benambra Highlands.... appear to be a greatly dissected pene-plain" (<u>op.cit.p.85</u>).

Consequent river valleys would, in early Tertiary times, carry enormous quantities of debris from the highlands to the If we assume that most of the East Gippsland area shore-line. was once a submerged portion of that vast peneplain of granodiorite (of Devono-carboniferous age) together with the still older (Ordovician) phyllite, then the present site of Mid West No.2 will represent a confined valley cutting through the southerly extension The arenaceous foraminifera found in the of the peneplain. granitic sands in varying numbers testify that those Lower Olligocene sediments were at times distinctly tidal and so have put their seal upon the relation of these particular granitic sands to the adjacent shore-line of that remote period. In these direction this valley can be visualised as generally coindiding with the present Tambo River Valley, which even now drains a

4

es similar region.

## COMPARISON OF BOTTOM SAMPLES FROM TWO ADJACENT BORES WHICH REACHED BEDROCK.

These are, Government Bore, No.1(3), which touched fairly solid Granodiorite at 1404 feet 6 inches, situated 150 chains to the S.W. of Mid West, 2, and the Lakes Entrance Development No.1 Bore, situated 200 chains E.N.E. which reached bedrock at 1215 feet, on what is probably Ordovician phyllite.

Having recently re-examined the core obtained by rotary drilling, from the bottom of the Govt.Bore 1(3), I make the following comments. The specimen is an almost cylindrical eore, abraded by the drill and fractured on one side. It measures 65mm.x 70mm. The rock is a yellowish, speckled granodiorite with biotite, two felspars and some quartz. It may represent a rounded boulder from a granite platform, but probably is close to bedrock.

The sediments lying immediately above the granite, at 1370 feet to 1390 feet, I have lately re-examined and now give the following amended description; having previously reported upon it on 9/3/29.-

A loose grey sand composed of fine and coarse quartz. A large percentage of the quartz grains are well rounded and wind-polished. Fragmentary fish remains, as bones and scales, together with teeth of <u>Carcharias victoriae</u>, <u>C.(Priodon)</u> <u>aculeatus</u>, <u>Heterodontus coleridgensis</u>, as well as neural spines and centra of vertebrae of teleostean fishes, and otoliths occur. The finer sand is composed of crystals of siderite. Numerous foraminifera are present, including <u>Haplophragmoides</u>, <u>Ammomarginulina</u>, <u>Ammobaculites</u>, <u>Spiroplectammina</u>, and <u>Lituola</u>, as well as the hyaline shelly form, Dyocibicides.

With regard to the bottom sediments from the Lake Bunga, Lakes Entrance Development No.l Bore, I have re-examined the sample at 1210 feet, overyling schistose bedrock at 1215 feet, and report as follows:-

Sample consists of brown and green sandy material, splintery fragments of greenish sericitic schist, ironstone sand particles and shelly fragments. The foraminifera determined are, <u>Guttulina</u> cf. <u>frankei</u>, <u>Epistomina elegans</u>, <u>Cibicides victoriensis</u>, <u>Globigerina bulloides</u>, <u>G.triloba</u>, <u>Haplophragmoides</u>, <u>Ammomarginulina</u>, <u>Ammobaculites</u>, <u>Discammina neocomiana</u>, <u>Trochammina</u>, cf. <u>Martinottiella</u>. <u>?Verneuilina</u>.

### OTHER GREAT THICKNESSES OF LOWER OLIGOCENE BEDS IN GIPPSLAND.

There is one other deep bore in Gippsland which compares in its excessive development of the Lower Oligocene with Mid West, No.2, nemely Tanjil Pt.Addis No.2, at Glencoe South.

There the Lower Oligocene was met with at 1303 feet and continued down to 2740 feet, thus giving a thickness of 1437 feet.

The Lower Oligocene in the Mid West bore runs it very closely with its 1431 feet 6 inches.

it Inthe former bore, however, appears to be a purely marine deposit, whilst in the latter it is of shallow water and terrigenous origin.

Although the Goon Nure Bore, N.of Lake Victoria, is a fairly deep one, of 2929 feet, only the last 269 feet were in the Lower Oligocene. In these samples of greenish grey pyritised marls, lignitic coal and puggy clay predominated.

DETAILS OF SAMPLES.

REPORT ON MID-WEST BORE. No.2.

LAKES ENTRANCE, GIPPSLAND.

11

REPORT ON MID-WEST BORE, No.2. LAKES ENTRANCE, GIPPSLAND.

1100 feet. (earlier samples not available).

Description. - Greenish-grey, micaceous and glauconitic foraminiferal marl. Fine Washings rich in Foraminifera; coarser, with a few molluscan shell-fragments and numerous ovoid pellets averaging

- 7 -

nisms.- F. frequent. C. common. V.C. very common. minifera.- <u>Glandulina laevigata; Cassidulina subglobosa;</u> <u>Reussella spinulosa;</u> <u>C. aff. crassa; Epistomina elegans; Anomalina glabrata;</u> Details of Organisms. -Foraminifera

ously ascribed to excreta of worms, holothuria or minute fishes.

1.75 mm. in longer diameter. Similar bodies have been vari-

Planulina ariminensis; Cibicides ungerianus; C.victoriensis; Globigerina triloba C; Martinottiella communis C. Anthozoa (Alcyonarian) - Mopsea sp. Echinodermata.- Small spines of sea-urchins, indet. Ostracoda - Cytheropteron batesfordiense; Cytherella lata.

1109 feet 11 inches.

Chips of hard grey limestone bands, with debris. Description.-Washings of material associated with chips, rich in Foraminifera. Coarser washings contain numerous pellets, chiefly glauconitic, and shelly fragments.

A thin section of the hard band shows a calcareously cemented foraminiferal coze containing a small proportion of minute angular quartz sand. The foraminifera in this hard band comprise numerous Globigerinae, their tests often infilled with glauconite.

Foraminifera in siftings are:-?Dentalina soluta; Lenticulina articulata; Guttulina problema; Cassidulina subglobosa;C; Discorbis bertheloti; Rotalia howchini; Epistom-Planulina wuellerstorfi; ina elegans; Cibicides refulgens; C.victoriensis; C.ungerianus; Hofkerina semiornata; Globigerina bulloides; Pulleniatina obliqueloculata; Elphidium verriculatum.

1121 Cect.

Description.- Greenish-grey, micaceous, glauconitic and sideritic foraminiferal marl.

Washings contain few foraminifera, an occasional echinid spine and test fragment, pieces of molluscan shells ampolyzoan and an ostracod. No pellets.

Details of organisms.-

Foraminifera.- <u>Cibicides victoriensis</u> C; <u>Martinottiella</u> <u>communis</u> F. Echinodermata.- Spines and test-fragments of salenids. Polyzoa.- <u>Canda fossilis</u>. Gasteropoda.- <u>?Personella</u>

Ostracoda.- <u>Bythocypris tumefacta</u>.

### 1131 feet.

Description.- Greenishgrey, micaceous, glauconitic and sideritic, for a miniferal marl.

Washings contain few pellets and abundant Foraminifera. Details of organisms.-

Foraminifera.- Lenticulina cultrata F; L.clericii; <u>Trifarina tricarinata F; Cassidulina subglobosa; Epi-</u> <u>stomina elegans; Anomalina rotula; Cibicides ungerianus</u>; <u>C. victoriensis C; Carpenteria proteiformis; Sphaeroidina</u> <u>bulloides V.C.; Globigerina triloba; Operculina sp.;</u> <u>Quinqueloculina vulgaris; Spiroloculina grata; Martin-</u> <u>ottiella communis</u> F.

Echinodermata.- Salenid spines F.

Polyzoa.- Fragments of cheilostomate forms, indet. Mollusca.- Shell fragments, indet.

### 1159 feet.

Description.- Grey micaceous foraminiferal marl, with ochreous stains.

Washings with minute Foraminifera and some glauconitic pellets.

Details of organisms.-

Foraminifera.- <u>Epistomina elegans;</u> <u>Planulina wueller</u>-<u>storfi;</u> <u>Cibicides victoriensis</u> C.; <u>Elphidium verricula</u>-<u>tum</u>.

Description.- Greenish-grey, shelly and micaceous foraminiferal marl, with much glauconite.

Washings contain numerous ovoid pellets, chiefly in glauconite.

Details of Organisms.-

Foraminifera.- Lenticulina calcar; L.cf.gyroscalprum; Cassidulina subglobosa; Anomalina rotula; Cibicides victoriensis; Elphidium verriculatum.

1231 feet 6 inches.

Description.- Hard, yellowish-green, glauconitic sandstone. Not examined in detail.

1234 feet.

Description.- Friable, glauconitic marl of a sage-green colour. Shelly fragments abundant, one more or less complete valve referable to <u>Ostrea</u> of.<u>hyotiodea</u>. This shell ranges from Upper Oligocene to Lower Miocene. Washed material consist largely of glauconite grains, represented by ovoid pellet**a** and casts of foraminifera; calcareous shelly fragments(bivalves); and also a few small rounded quartz grains. The finest washings consist mainly of minute foraminifera in siderite and **gx** glauconite.

1237 feet.

Description.- Hard, yeldowish-green, glauconite sandstone. Washings show numerous calcareous shelly fragments; pellets and foraminiferal casts in glauconite; also carapaces of ostracoda and tests of foraminifera.

Details of Organisms. - Foraminiform. -

Foraminifera.- <u>Anomalina</u> cf. <u>glabrata</u>. Ostracoda.- <u>Cythere</u> sp; <u>?Bythocythere</u>.

1239 feet.

Description.- Dull green, hard glauconitic sandstone, with shelly fragments on surface of rock. Washings chiefly contain glauconitic casts of foraminifera and green platy fragments resembling vermiculite. Details of Organisms.-

Foraminifera. <u>Cibicides ungerianus;</u> <u>C.victoriensis</u>. In both species the calcareous test is preserved. Ostracoda.- <u>Cytherella punctata(in glauconite)</u>.

### 1240 feet.

Description.- Dark brown, gritty, ferruginous rock. Washings show a large proportion of angular quartz, associated with rusty flakes of hydrated iron oxide. (This sample appears to have been contaminated by the accidental introduction of iron from outside). No glauconite seen.

### 1241 feet 66inches: 3.

Description.- Moderately hard to friable glauconitic sandstone, of a pale sage-green colour. Coarse washings with shelly fragments( brachiopods) and rounded quartz grains. Fine washings with numerous small foraminifera, hav-

ing calcareous tests. Glauconite grains with casts. Details of Organisms.-

Foraminifera.- <u>Guttulina</u> sp.; <u>Cassidulina subglobosa</u>; <u>Gyroidina soldanii; Epistomina elegans; Planulina</u> <u>wuellerstorfi; Cibicides ungerianus; C. victoriensis;</u> <u>Pullenia sphaeroides; Pulleniatina obliquiloculata</u>;

1243 feet 6 inches.

Description .- Hard, yellowish-green, slightly micace-

ous glauconitic sandstone. Not examined in detail. Not examined in detail.

1245 feet 6 inches.

Description.- Friable, micaceous glauconitic sandstone, sage-green in colour. Washi Washings contain some rounded and subangular quartz grains. Glauconite and siderite abundant; also some mica flakes. Foraminifera rare in the finer siftings. Details of Organisms.-

Foraminifera.- Rotalia howchini; Cibicides ungeria

nus.

Bescription - Hard, light sage-green glauconitic sandsk sandstone. Also a darker green and more friable sample sample; washed.

Washings consist of rather irregularly shaped glauconite grains. Some ovoid pellets in glauconite, wellrounded quartz grains and mica flakes. Foraminifera, minute.

Details of Organisms.-

Foraminifera .- Cibicides ungerianus.

1247 feet 6 inches.

Description.- Hard, pale sage-green glauconitic sands stone, with a few fragments of softer texture. Not examined in detail.

1249 feet 6 inches - 1251 feet 6 inches.

Description.- Hard, fine-grained glauconitic sandstone, of a sage-green colour, slightly brown on the weathered surface.

Crushed material shows a large proportion of glauconite grains, several recognisable as foraminiferal **EX** casts (cf.<u>Cibicides lobatulus</u> and aff.<u>Globigerina</u>); a small percentage of rounded quartz pebbles averaging 1 mm. in diameter; numerous subspherical or ovoid pellets of a greenish-brown colour averaging .75 mm. in diameter; crushed fragments of fibrous or platy material resembling vvermiculite averaging .75 mm. in dresstsection.

A thin section shows a cavernous matrix having a large proportion of glauconite(with brown tints **ANR** under transmitted light. Many of the grains show the form of the casts of internal chambers of foraminifera(rotalines, <u>Globigerina</u>, etc.). A fair quantity of angular, transparent quartz is present.

N.B.- This sample is foreign to the glauconite horizon and appears to come near to the 1466 feet horizon.

> Description.- A rust-coloured or pinkish sand, consisting of sharply angular quartz grains with some gypsum(ds (dissolving in warm H Cl) and numerous flakes of green chloritic mineral. No glauconite. Casts of foraminifera in anhydrite.

Details of Organisms.-

Foraminifera. - Chalky isomorphs of Lenticulina planiuscula and ?Flabellina.

1251 feet 6 inches- 1252 feet 6 inches.

Description - Friable, sage-green, slightly micaceous, glauconitic sandstone.

Coarse washings contain numerous, fairly large, rounded quartz grains and aggregated glauconitic particles. Finer washings with quartz, glauconite and remains of foraminiferal casts.

1253 feet 6 inches- 1254 feet 6 inches.

Description.- This sample includes two somewhat different types of rock. One of these is a friable, darkgreen glauconitic marl, the other a more carbonaceous and smoky black variety. The latter partially burns away when heated on platinum foil, leaving a cavernous matrix.

Washings consist of glauconitic particles with some siderite and numerous rounded quartz grains, averaging 1 mm. in diameter.

### 1257 feet 6 inches.

Description.- Brownish-green, hard, glauconitic sandstone. Cut surface with a greasy lustre.

Coarse washings with glauconite and siderite in aggregates. Numerous rounded and flattened quartz pebbles; also a few angular quartz graind. Pellets in glauconite not uncommon. Foraminifera **sa** obscure casts. 1257 feet 6 inches- 1259 feet 6 inches.

-7-

Description.- Hard, pale-greenish glauconitic and calcarea ous sandstone.

Washings show numerous sideritic particles and fragments of dark-brown organic structures. Also some rotaline foraminifera, indet.

N.B. No samples available to bridge this long gap.

### 1466 feet.

Description.- White quartz sand, with limonite and chloritic flakes. Gypsum and apparently calcite or aragonite is present in these and other sand samples beneath, which probably represent the chemically changed calcareous tests of foraminifera, leaving only the minute arenaceous forms in these sands.

This particular sample seems to have been derived from a rock similar to a chloritic schist. Fine washings consist of angular quartz sand and occasional arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- Trochammina spp.

N.B.

This sample may compare, in a general way, with the erroneously placed "1250".

### 1484 feet.2 inches.

Description.- The same as the preceding. With obscure foraminifera.

Details of Organisms.-

Foraminifera.- cf. Cassidulina; cf. Trochammina.

1487 feet 3 inches.

Description.- White and brown speckled sand, containing quartz, chlorite and mica.

Details of Organisms.-

Foraminifera.- <u>Discorbisispes Blanulina wuelle</u> erstorfi; <u>Discammina spes</u> <u>Trochammina spe</u> Pisces.- Scale of fish, indet.

1487 feet 6 inches.

Description.-

White quartz sand with limonite.

Washings show flakes of Biotite and chlorite in nearly equal proportion. The quartz is angular; some felspar present.

Details of Organisms.-

Foraminifera.- Trochammina sp.

Ostracoda .- Cast of carapace, indet.

1488 feet 11 inches.

Description. - White and brownish quartz and limonitic sand, with chlorite and biotite.

Details of Organisms.-

Foraminifera .- cf. Calcituba; cf. Trochammina.

1489 feet.

W

Description.- Fine grey quartz sand, with some limonite, biotite and a little chlorite. Also obscure foraminifera.

Details of Organisms.-

Foraminifera. - Ammomargimulina sp.

1491 feet.

Description.- Fine grey to brown sand. Fine angular quartz sand predominating; also limonite, and biotite abundant; occasional fragments of bright green chlorite; felspar(plagioclase) rare.

Details of Organisms.-

Foraminifera.- <u>Psamhonyinsperie</u> <u>Discammina</u> spe; ?<u>Plac-opsilina;</u> <u>Trochammina</u> spe

1493 feet.

11-

Description.- Fine grey granitic sand, with angular quartz, pink felspar, and brown to greenish mica. This sample, with its chalky(?anhydrite) particles and arenaceous foraminifera, closely resembles the Lower Oligocene of other bores.

Details of Organisms.-

Foraminifera.- <u>Ammobaculites</u> sp.; <u>Trochammina</u> sp. 1530 feet.

Description.- Fine, grey, granitic sand, with chlorite. Amongst the coarser particles fragments of pink gran-9-

Details of Organisms.-

1554 feet.

Description.- Greyish brown granitic sand, of very fine texture. Containing quartz, chlorite, biotite and limonite. Arenaceous foraminifera frequent.

Details of Organisms.-

Foraminifera.- <u>Ammobaculites</u> sp.; <u>Discammina</u> sp.; <u>Trochammina</u> sp.

1576 feet.

Description.- Speckled grey sand, containing limonite and biotite. Finer washings contain frequent tests of minute arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- <u>Ammobaculites</u> sp.; <u>Trochammina</u> sp.; <u>Verneuilina</u> cf. <u>tricarinata</u>.

1584 feet.

Description.- Greyish-brown granitic sand with quartz, biotite and limonite.

Pinop

Finer washings contain minute arenaceous foraminifera. Details of Organisms.-

Foraminifera.- <u>Trochammina</u> sp. and other, indeterminate forms.

1607 feet 5 inches.

Description.- Fine rock debris of a granulitic character, consisting chiefly of quartz, plagioclase felspar and biotite.

Fine washings contain minute crystals of gypsum, an occasional glauconite grain and some minute foraminifera.

Details of Organisms.-

Foraminifera.- Trochammina sp.

Description.- Fine greenish-grey granitic sand, with quartz grains, flakes of biotite and particles of limonite. Foraminifera in the finest washings. Details of Organisms.-

Foraminifera.- <u>Trochammina</u> sp. frequent.

1626 feet 6 inches.

Description.- Fine brownish-grey granitic sand. Occasional minute foraminifera.

Details of Organisms.-

Foraminifera. - Trochammina sp.

1639 feet.

Description.- Dark brownish-grey granitic sand, with quartz, biotite, plagioclase felspar and limonitic particles.

Details of Organisms.-

Foraminifera.- <u>Trochamminoides</u> sp. <u>Ammomarg</u>inulina sp. <u>Discammina</u> sp.

1663 feet.

Description.- Grey granitic sand with ochreous tint. Quartz, much pink felspar, biotite(green to brown) z and chlorite. Minute foraminifera.

Details of Organisms.-

Foraminifera .- Trochammina sp.

1674 feet.

Description.- Grey granitic sand with quattz, biotite and chlorite. Arenaceous foraminifera common Details of Organisms.-

Foraminifera.- Flabellammina sp:; Discammina sp. sp. Trochammina sp.

1679 feet.

Description.- Grey granitic sand with reddish tint, consisting of quartz, pink felspar, and biotite. Arenaceous foraminifera rare.

Details of Organisms.-

Foraminifera .- Trochammina sp.

-10-

Description .- Grey granitic sand, with a large proportion of

floury quartz sand. When tested proves to be slightly calcareous.

Details of Organisms .-

Trochammina sp. Foraminifera.-

1752 feet, 11 inches.

Description -Similar to preceding. Details of Organisms.- cf. Tpochammina.

1779 feet.

Description .- Pinkish brown, fine and coarse granitic sand, containing quartz, pink and white felspar, biotite and limonite as deposit on grains. Finer washings contain foraminifera.

Details of Organisms.-

Foraminifera.- cf. Discorbis; cf. Psammonyx; Ammomarginulina sp.; Spiroplectammina sp.

1780 feet.

Description -Fine, whitish, detrital sand, with larger fragments of quartz and Biotite. Also irregular lumps of pale greenish concretions, reacted upon by cold HCl. Foraminifera excessively minute.

Details of Organisms.-

Foraminifera.- Haplophragmoides sp.; Trochammina sp. 1787 feet

Description .- A grey, granitic sand, with quartz and biotite. Foraminifera in the finest siftings.

Details of Organisms.-

Foraminifera.-Trochammina sp.

1842 feet.

Description - Fragments of ?hypabyssal rock, possibly Epidiorite, containing altered pyroxene and a little quartz.

1844 feet.

Description .- A detrital, granitic puble, showing

quartz, pink felspar and much biotite; also some pyroxe ene.

### 1846feet.

Description - Similar to preceding, but in larger fragments.

1852 feet.

Description.- Grey, granitic sand, with much biotite and limonitic encrustation.

Details of Organisms.-

Foraminifera.- <u>Trochamminoides</u> sp.; <u>Discammina</u> sp. 1870 feet.

Description.- Grey, granitic sand, similar to above. Arenaceous foraminifera present, indet.

1875 feet.

Description .- Similar to above.

1883 feet.

Description.- Granitic sand, with the addition of pink felspar.

Details of Organisms .-

Foraminifera. - Trochammina sp.

1885 feet.

Description.- Grey, granitic sand, with quartz, pink felspar and biotite.

Details of Organisms.-

Foraminifera .- Discammina sp.; Trochammina sp.

1894 feet 6 inches.

Description.- Grey, granitic sand as above, with obscure foraminifera, indet.

1895 feet.

Description.- Pink, granitic sand, with quartz, felspar, biotite and chlorite. Showing a slight reaction with cold HCl.

Details of Organisms.-

Foraminifera.- Discammina sp.; Trochammina sp.

Description.- Grey speckled granitic sand, consisting of quartz(angular and rounded), white and red felspar, biotite and chlorite.

Details of Organisms.

Foraminifera.-

1903 feet.

Description.- Ditto. • Foraminifera fairly common. Details of Organisms.- cf.<u>Trochammina</u>, etc.

1908-9 feet.

Description.- Ditto. Foraminifera frequent. Details of Organisms.-

> Foraminifera.- <u>Trochamminoides</u> **s**p;; <u>Haplophragmo-</u> <u>Ammomarginulina</u> sp.; <u>ides</u> sp.; <u>Clobivalvulina</u>.

Trochammina sp

1913 feet.

Description - Ditto.

Details of Organisms .-

Foraminifera.- <u>Trochamminoides</u> sp.; <u>Haplophrag</u>-<u>moides</u> sp.; <u>Ammomarginulina</u> sp.; <u>Discammina</u> sp.; <u>?Placopsilina</u>.

1916 feet.

Description - Ditto.

Details of Organisms .-

Foraminifera.- Haplophragmoides sp.; Ammomarginulina sp.; Ammobaculites sp.; ?Placopsilina.

1926 feet.

Description - Coarse, grey, speckled granitic sand, with occasional foraminifera.

Details of Organisms.-

Foraminifera.- Trochammina sp.

1951 feet.

Description.- Excessively fine, white sand, with angular quartz and felspar, both orthoclase and plagioclase, with perthite structure not uncommon, and a few flakes of biotite. Some calcareous matter present. No foraminifera seen.

1951 feet 6 inches.

Description.- Grey, granitic sand, fine and coarse. Quartz, felspar( some pink fragments) and biotite. Minute foraminifera present.

Details of Organisms.- of

Foraminifera.- cf. Trochammina.

1960 feet.

Description - Grey speckled granitic sand with angular quartz, pink felspar and biotite.

Details of Organisms.-

Foraminifera.- Psammonyx sp.; Discammina sp.

1961 feet.

Description - Pinkish-grey speckled granitic sand, with angular quartz, pink felspar, biotite and a little limonite in pustulate particles.

Details of Organisms.-

Foraminifera.- Discammina sp.; cf. Trochammina.

1962 feet.

Description.- Grey, granitic sand, with quartz, some felspar, biotite and chlorite. Amongst the finer sand ocred a doubly terminated zircon.

Details of Organisms.-

Foraminifera.- cf.<u>Discorbis</u>(glauconite cast); <u>Lit</u>-<u>uotuba</u> sp.; <u>Haplophragmoides</u> sp.; cf.<u>Placopsi</u>lina.

1968 feet.

Description.- Grey speckled, granitic sand, with angular quartz, some felspar and much biotite. Occasional foraminiferal casts in glauconite and arenaceous forms.

Details of Organisms.-

Foraminifera.- cf.Flabellammina; Discammina sp; Trochammina sp.

Description.- Grey to pink coarse and fine granitic sand, with angular quartz, some felspar(pink and white) and biotite, and a little chlorite and sericite. Arenaceous foraminifera frequent.

Details of Organisms.-

Foraminifera.- <u>Ammomarginulina</u> sp; cf.Flabellammina; Discammina sp.

1978 feet.

Description -- Grey to pink, coarse and fine granitic sand, with angular quartz, felspar and biotite.

Details of Organisms.-

Foraminifera.- cf. Agathammina; ?Haplophragmoides.

1980feet.

Description.- Grey speckled granitic sand, with angular quartz, felspar and mica.

Details of Organisms.-

Foraminifera.- <u>Discorbis</u> sp.; <u>Psammonyx</u>; cf.<u>Ag</u>athammina; <u>Spiroplectammina</u> sp.

1982 feet.

Description.- Grey speckled granitic sand, with chief ly angular quartz and biotite; also occasionally fafelspar and rarely actinolite.

Details of Organisms. - cf. Agathammina; Discammina sp.; Trochammina spp.

2001 feet.

Description.- Grey granitic sand with much fine detritus. Effervesces in cold HCL. Details of Organisms.- cf.<u>Ammomarginulina</u>; cf. <u>Flabellammina</u>; <u>Discammina</u> sp.

2083 feet.

Description.- Grey detrital mud, yielding after washing a fine granitic sand, with small aggregated particles of limonite, and minute arenaceous foraminifera. A large percentage of carbonate of lime present. Details of Organisms.-

> Foraminifera.- <u>Ammobaculites</u> sp.; <u>Ammosphaeroidina</u> sp. cf. <u>Valvulammina</u>.

2101 feet.

Description - Grey speckled granitic sand. Angular quartz, biotite and some limonite. A small quantity of calcareous matter present.

Details of Organisms.-

Foraminifera.- <u>Heronallenia</u> cf. <u>lingulata</u>; <u>Haplophrag</u>. <u>moides</u> sp.; <u>Discammina</u> sp.; <u>Trochammina</u> sp.

2109 feet.

Description.- Greenish-grey granitic sand. Sand grains **Descured** with fine detritus. Washed **in**aterial shows quartz, chloritic and micaceous flakes, limonite and probably fragments of pink felspar. Numerous minute foraminifera. Some small, ovoid or flattened pellets of a pale green colour present, bearing resemblance to casts of ostracod carapaces.

Details of Organisms.-

Foraminifera.- <u>Ammobaculites</u> sp.; <u>Discammina</u> sp.; <u>Tro-</u> <u>chammina</u> **sp.**;

2128 feet.

Description.- Grey speckled granitic sand, with quartz, biokx tite and felspar. Occasional ovoid,greenish mud pellets. Details of Organisms.-Foraminifera.- ?Psammonyx; Discammina sp. F.

2132 feet.

Description.- Grey speckled granitic sand, with quartz, biotite and some felspar; also particles and encrustations

of limonite.

Details of Organisms.-

Foraminifera.- <u>Heronallenia</u> cf. <u>lingulata;</u> <u>Psammonyx</u> sp.; <u>Discammina</u> sp.; <u>Trochammina</u> sp.

2138 feet.

Description.- Grey speckled granitic sand, with quartz, bioz tite and some felspar; also occasional particles of Details of Organisms.-

Foraminifera.- <u>Ammomarginulina</u> sp.; <u>Discammina</u> sp.; **Tr** <u>Trochammina</u> sp.

2139 feet.

Description.- Ditto, with both calcareous and arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- <u>?Lenticulina</u>(mineral replacement); cf. <u>Siphonina</u> xx.; cf. <u>Globorotalia</u>; cf. <u>Stacheia</u>.

2142 feet.

Description.- Ditto, with pink felspar and ?garnet. Also calcareous and arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- <u>Epistomina</u> sp.; cf. <u>Siphonina</u>; cf.<u>Amph-istegina</u>; <u>Discammina</u> sp.; <u>Spiroplectammina</u> sp.; <u>Troch-ammina</u>.

2143 feet.

Description.- Fine grey, granitic sand, chiefly angular quartz and some biotite. Washings show both calcareous and arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- <u>?Heronallenia</u>(glauconite cast); <u>Cibici-</u> <u>des cf.lobatulus; Psammonyx</u> sp.; cf.<u>Nubecularité, Ammo-</u> <u>marginulina</u> sp.; <u>Discammina</u> sp.; <u>Spiroplectammina</u> sp.; <u>?Spiroplectinata</u>.

Ostracoda .- Cythere sp.

### 2152.feet.

Description.- Fine granitic sand of a pinkish tinge. Quartz, biotite and some chlorite. Foraminifera rare. Details of Organisms.-

Foraminifera.- Casts of rotalines, indet.; cf.<u>Discammina;</u> Spiroplectammina sp.

Description - Fine, grey, granitic sand, with quartz, pink felspar and biotite.

Details of Organisms .-

Foraminifera.- <u>Discammina</u> sp.; <u>Spiroplectammina</u> sp.; Trochammina sp.

2162 feet.

Description - Very fine white quartz sand, with a few flakes of biotite. No foraminifera.

2174 feet.

Description.- White speckled granitic sand, with quartz,felspar, biotite and some chlorite. Foraminifera very rare. Details of Organisms.-

Foraminifera. - Trochammina sp.

2181 feet.

Description - White speckled, granite sand, with quartz, white felspar, biotite and some limonite. Foraminiferal sast, indet.

2196 feet.

Description .- Fine to rubbly, pink and green granitic sand. Larger particles up to 8 mm. in diameter. Examined in detail, the larger pieces appear to be referable to a green augite syenite, with pink orthoclase and white, partially kaolinised felspars, enclosing allotriomorphic quartz. Patches of a dark green fibrous mineral may be referred hornblende to partially attante augite passing into antorite. Other fragments, showing a dull greencolour and waxy texture, may be of the nature of epidote. Similar rocks to these fragments have lately been described by Messrs.E.Broadhurst and J.D.Campbell(Proc.Roy.Soc.Vict. 1933, vol.XLV.pt.II. pp.223,224) under the heading of Granodiorites and Associated Gneisses, from the Mt.Leinster region of N.E.Gippsland.

The finer siftings from this depth, the samples of which in Lightner's log as"very changeable", consist of angular to subangular sand grains, with smaller rounded ones also numerous pale-green granules of rounded or ovoid contour, resembling casts of foraminifera in glauconite. A few arenaceous foraminifera.

Details of Organisms.-

Foraminifera.- ?<u>Marginulina</u>(transparent cast); cf.<u>Hemigor</u>-<u>dius;</u> ?<u>Discammina;</u> ?<u>Spiroplectammina;</u> (also a ?cast of the latter in glauconite).

2200 feet.

Description - Fine, grey, speckled granitic sand, with angular quartz, fragments of pink and white felspar, biotite and vivid green chlorite. No foraminifera noted.

2204 feet.

Description.- Ditto.

2206 feet.

Description.- Ditto. Foraminifera minute and rare. Details of Organisms.-

Foraminifera .- 9, Trochammina .sp.

2210 feet.

Description.- Very fine, grey, granitic sand. Details of Organisms.-

Foraminifera .- Trochammina sp.

2212 feet.

Description - Ditto.

Details of Organisms.-

Foraminifera .- ?Discammina; Trochammina sp.

2216 feet.

Description.- Fine, grey, granitic sand, with angular quartz, Orthoclaseand plagioclase felspar, olive green to brown mica, apatite and chlorite. The fespar often shows perthite structure. For aminifer a fairly frequent. Details of Organisms.-

Foraminifera.- cf.<u>Virgulina; Hemidiscus</u> sp.;cf<u>Agath</u>ammina; <u>Discammina</u> sp.; <u>Spiroplectammina</u> sp.; <u>Tro-</u> chammina sp.

Description.- Fine, grey, granitic sand, with quartz, felspar and mica (biotite abundant, muscovite rare).

Details of Organisms.-

Foraminifera.- cf. Agathammina.

2221 feet.

Description - Ditto.

Details of Organisms.-

Foraminifera.- <u>Ammomarginulina</u> sp.; cf.<u>Discammina</u>; cf.<u>Trochammina</u>.

2228 feet.

Description - Ditto.

Details of Organisms.-

Foraminifera.- ?<u>Agathammina; Placopsilina</u> aff. <u>cenomana;</u> ?<u>Spiroplectammina; Trochammina</u> sp.

2237 feet.

Description.- Grey speckled granitic sand, with angular quartz, brown and occasionally white mica. Foraminifera minute, numerous.

Details of Organisms.- <u>Reussella</u> sp.; <u>Discorbis</u> sp.; <u>Ammobac</u>-Foraminifera.-

ulites sp.; Discammina sp.

2250 feet.

Description.- Grey quartz sand with biotite; excessively fine, with numerous foraminifera.

Details of Organisms.-

Foraminifera.- Hemidiscus sp.; Ammomarginulina sp.;

Discammina sp.; Arenobulimina sp.

2255 feet.

Description.- Fine grey quartz sand with biotite, a little chlorite and ?augite. Foraminifera rare. Details of Organisms.-

Foraminifera.- Discammina sp.; Trochammina sp.

Description.- Greyish brown granitic sand, with quartz, some felspar, abundant biotite and chlorite. Much limonitic staining of particles.

Details of Organisms.-

Foraminifera.- Discammina sp. F.;

-21

-2478 feet.

Description - Rubbly particles, up to 1 cm. in diameter, consisting of decomposed granodiorite and gneiss.

2490 feet.

Description - Coarse, speckled, granitic sand, apparently derived from the same source as the preceding sample; we containing abundant quartz, some plagioclase and orthoclase(pink), biotite and chlorite.

2528 feet.

Description.- Grey speckled sand, with much clear angular quartz, biotite flakes(not associated with chlorite), some kaolinised felspar, hornblende and augite. Details of Organisms.-

Foraminifera.- Discammina sp.

2560 feet.

Description.- Ochre-coloured quartz sand, with biotite, and decomposed felspar and limonite. Foraminifera very rare. Details of Organisms.-

Foraminifera.- Discammina sp.

2566 feet.

Description.- Grey, excessively fine to gritty sand. In the coarser portion the quartz is rounded to subangular; some mica(biotite) and chlorite. Arenaceous foraminifera frequent.

Details of Organisms .-

Foraminifera.- <u>Haplophragmoides</u> sp.; <u>Ammobaculites</u> **sp.;** sp.; <u>Discammina</u> sp.; <u>Trochammina</u> sp.

Description.- Fine speckled grey granitic sand, with quartz and biotite in nearly equal proportions. Arenaceous foraminifera common.

-22-

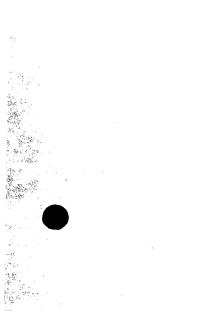

Details of Organisms.-

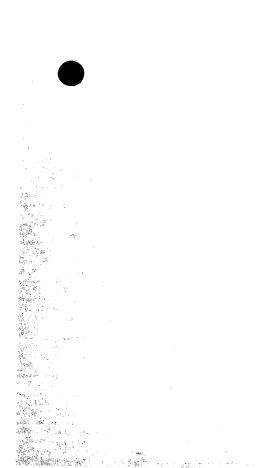

Foraminifera.- <u>Haplophragmoides</u> sp.; <u>Ammomarginulina</u> sp.; <u>Discammina</u> sp.; <u>Trochammina</u> sp.

3203 feet.

Description. - Decomposed granodiorite with pink felspar and much chlorite and biotite.

	1880'	<b>**</b>	1931.'	-	very fine and compact - same formation as at 1840' to 1850' - cuttings showed oil and gas (wet gas) for first time in history of field (from 1902'3" to 1926'9")
	1931 '	11	2025'	**	resembling red permian beds - well worn felspar, and quartzoe, show signs of travel.
	2025'	<b>91</b>	2067*	1238	very sandy and highly cemented - same small pebbles.
	2067 '	<b>31</b>	2108 '	-	granitic sands - very little mica - also show signs of travel by the rounded corners of the grains - much lime and active gas.
	2108	11	2110'	-	alternating fine and coarse - very limey
	2110 *	11	2147'	 440	conglomerate, with crystalline of lime
	2147'	¥7	2180 '	<b></b>	much softer formation, cuttings not settling in water very rapidly
	2180'	11	22031		very changeable
	22031	а. Д	22051		water sand, resembling old creek bed
	2205	ŧ	2240		fine granitic sand, with lime
	2240 '	Ħ	2252		greyish blue shale
	2252 1	11	2275	-	granitic sand
	2275	ù	22901		conglomerate of sand and pebbles
		ι. AL			

	2290 °	to	23401		- hard <b>i</b> linty rock
	2340 *	11	2370'		- rotten green stone and gas
	2370	ŧ	2408 1		- hard flinty grey rock
	24081	ij	2422*		- sandy cemented formation
	2422*	11	2440		- water washed pebbles, sand with gas
	2440 *	11	24831		- quartz, pebbles, conglomerate and more gas
	2483	#	2500 <b>'</b>		- same as 2440' to 2483'
	25001	H	2560*		- grey rock, showing lime veins
	2560 1	Ħ	2582 '		- conglomerate pebbles with lime
	25821	11	2640 *		- conglomerate, gas
	26401	Ŭ	2680*		- hard and flinty, lost drilling tools, but were recovered, hole went crooked andwas redrilled from 2671'.
	2680 1	#	26 <b>91 '</b>		- grey shale apparently tilted - gas.
	Casing 4	Wa	as set	at	2656*10".
	2691	to	27361		- granitic formation (not hard)
-	27361	Ħ	28801		- fine granitic sand with hard and soft bands, and at 2752' gas burns on tub when bailer dumped.
	2880				- working into change
	3300 '		•		<ul> <li>blue grey interlaced with thin bands of felspar - gas strong</li> </ul>
	3379*				- same formation, cuttings appear like sandy grey shale. Water level here dropped to 400' from surface.
	3400 '				- similar formation, water level dropped.to 560' from surface, indicating that the formation is taking water. Previous to this decrease, the water level was within 100' of top of casing. Cuttings similar to 3379' - appear like sandy grey shale.

-4-

Drilling ceased at 3400' on May 5th, 1935, with string of tools which were abandoned at bottom.

As shown on Log, this well had been drilled into oil sand at 1227\* on to 1255 feet into bottom water, but before taking steps to plug off this water, the new Superintendent desired to drill ahead to test the underlying structure as to whether it was bedrock or not. He was definite in his opinion that his experience overseas justified him in forming other conclusions and that a further testing of the lower strata was justified.

Mr. Frederick Chapman's report on the samples of structure down to 2,590' may yet prove the correctness of the aforesaid conclusion. The total depth drilled reached 3,420 feet.

In course of time, this Company had to suspend operations temporarily. On resuming, it was decided to plug off the well immediately above the bottom water and test the oil sand for production. Tests are now being carried out in this direction and a steady improvement is taking place.

From 16/8/37 to 6/12/37, bailed 11,518 gals. fluid, 2,070 gals. oil.

12416

Samples and Rock Chips from Mid West Bore No.2 (depth, 1742 ft.).

Collected by Mr.J.W.Binney.

Slide Nos.2780,2781 & 2786

## 2786

The larger pieces were ground and mounted. Under the microscope these are undoubtedly a granite. The rock consists essentially of felspar, mica and quartz. The felspar is saussuritised and oligoclase, microcline and orthoclase are present. The mica is an olive brown variety which shows alteration to chlorite. In some cases this alteration has proceeded a great deal; in others the mica is untouched. Apatite and iron ores occur as accessories.

## 2780-2781

The sand was treated with dilute hydrochloric acid. The effervescence was very small so that the amount of carbonates was very small. After washing, the sand was treated with a magnet to separate the large amount of iron filings that are present. Some of the effervescence with hydrochloric acid is probably due to the action of the acid on the iron.

The sand was dried and then separated by bromoform into a light and heavy fraction.

<u>Sl.2780</u> - <u>Light Fraction</u>. This consists essentially of angular grains of plagioclase, with fine albite twinning, and some orthoclase and quartz. Biotite and chlorite are present in small amounts.

S1.2781 - Heavy Fraction. This consists of a dark brown mica (biotite with a rseudo-uniaxial interference figure) chloritized mica, chlorite. Common hornblende

and a pale epidote occur sparingly. All the minerals present are normal for the granite and there is no doubt that the sand is the crushed granite represented by S1.2786.

This rock was compared with the granite outcropping near Colquhoun North (S1.2106) and that occurring at the bottom of Bore 2 (Lake Bunga) near lakes Entrance, and under the microscope the rocks are identical.

Some of the granite from Bore 2, Lakes Entrance, was crushed and treated in the same manner as the sand from Mid West Bore No.2.

S1.2776 - Light Residues

This consists of angular quartz, plagioclase, microcline and a little biotite.

<u>Sl.2777</u> - Heavy Residues A flood of olive brown biotite, in part altered to a green chlorite.

Under the microscope, these slides cannot be separated from those of Mid West Bore No.2.

Some of the undoubted sand lying on top of the granite at Bore No.1, Colquhoun North, was examined. This sand is undoubt-edly derived from a granite but S1.2785 (heavy fraction), Bore No.1, Colquhoun North, is a much lighter crop and shows a much greater proportion of zircon, apatite than mica. In the lighter residue the percentage of quartz is greater than in Mid West Bore. Several other slides of the sandy limestone from some of the other bores were examined.

The sand from the Mid West Bore No.2 (depth 1742 ft.) is undoubtedly derived from the rock represented by S1.2786. This granite is identical with that outcropping at Colquhoun North, at that obtained at the bottom of Bore No.2, Colguhoun North, and No.1

W416

Bore,Lakes Entrance. In the proportion of the heavy minerals present it is different from any of the sands obtained in the bore.

-2-

There is thus no doubt that the sand represents a crushed granite.

(S'd) D.E.THOMAS 9/4/32: MID-WEST BORE NO 2.

W4/6

NOTES OF AN EXAMINATION OF A SAMPLE OF "SLURRY" OBTAINED FROM THE BAILER AFTER CEMENTING OFF AT THE 1255 ft. LEVEL.

The sample now examined has been previously subjected to boiling, to obtain material free from oily constituent. This material is pale grey, fine-grained and powdery for the most part. It has less than 20% of coarser aggregated particles which measure up to 0.5 mm. The excessively fine material, microscopically examined, in some ways resembles finely ground cement("Bull-dog Brand" examined for comparison), but that the latter is untouched by weak, cold HCl, whilst the slurry sample is in the main dissolved by the reagent, which leaves a residue of fine terrigenous granules.

The intermediate, coarser, portion of the slurry, about 50% consists almost entirely of foraminiferal shells, such as are met with in the micaceous series above the glauconite sandstone.

The glauconitic band from Govt.Bore No.l was examined for comparison, but this yielded very few tests of foraminifera and did not in any way compare with the slurry, where glauconite was almost entirely wanting or only represented by very minute grains.

CONCLUSION.- The slurry is an almost pure deposit of organic particles, mainly tests of foraminifera, together with a few echinoid spines, sponge spicules and other fossil fragments. The only evidence for the presence of cement possibly lies in a small percentage, perhaps 1 or 2% of the fine powdery part of the sample.

The bulk of the slurry, therefore, seems to have been derived from the micaceous sands above the glauconite bed.

It may be remarked, in addition, that in the log of Mid-West No.l, at 1260' "Strong gas" is noted. This section is succeeded downward by dark clay with little sand to 1280', when 30 feet of Glauconite oil-sand is recorded.  $\mathcal{F}$ . Chapman  $\mathcal{S}/8/37$

PRODUCTION RECORDS

4 Derby Street, CAMBERWELL E.6 24/9/1937

C.S.Demaine Esq., Acting Managing Director Austral Oil Syndicate, MELBOURNE.

N 4/b

Dear Mr Demaine,

At Mr Chapman's request, I am forwarding herewith a copy of the log of the Midwest No. 2 bore. It is just as I copied it from Lightner's record, & I have made no attempt to make it more intelligable. Personally, I think that the log has very little practical value, as some of the determinations have obviously been made by someone quite unfamiliar with geological terms. However, there it is, for what it is worth.

I think I am now in a position to suggest some bore sites near Foster's bore,or perhaps it would be more correct to say that I could adwance a few reasons why bores should be located at some points in preference to others. I would like to be able to be more definite, but you are as aware of the inadequacy of the records as I am, and will appreciate the difficulty.

I had a chat with Mr Chapman on Tuesday, and I find that our figures agree on all material points except for the No. 8 bore, where there is a variation of 50 feet between his figures and mine. He has taken the figures given in the Departmental publication, whilst I have taken those supplied to me by Messrs Imray & Lightner last year, and which, I think, fit in better with the data from adjoining bores.

> With kind regards, Yours faithfully

I.C.H.CROLL

D NOTES DRILLING MIDWEST No.2. BORE From 11/9/31 to 12/9/32. FIELD NOTES

W416

1931 Sept.	11	1227'	Struck oil sand - cored to 1228 ft. with very good show of oil - gas very strong to oil sand and increased after coring one ft. Reaming hole to 10 inches before cementing. Cemented 11th instant.
	18	1231'	Gas pressure blew the glauconite out additional 3' 6" causing casing to slip down for that distance. Recementing at 1231 - splendid show of oil and gas.
Oct.	2	1241' 6"	Drilled through cement - water shut off - Cored 10 ft. 6 ins. into oil-sand and reamed hole to 10 inches. Splendid show of oil.
	9	1255	Water shut off. Cored 27' 6" into rich oilsand and reamed to 10". Bailed 260 gallons fluid for 200 gallons oil.
	16	1257	Bailed 370 gals. fluid for 270 gals. oil in 5 days. Cored 2 ft. deeper into oilsand.
	24	1314	Bailed 75 gallons oil on 16th. Cored and drilled 7" hole to 1314 in fine and coarse sand - gas very strong and burns in bailer.
	30	1345' 7"	5" casing to 1339' 4" - 1339' 4" to 1345' 7" very hard grey formation. Gas burns in bailer.
Nov.	6	1361'	Hard red and grey formation - gas.
	13		Mr. Lightner fired 2 charges.
	21		Filled to 1334' 6" as casing would not turn. Redrilled to 1347'.
	27		Redrilled to 1359
Dec.	4	1364	In hard red and grey formation.
	11	1366 ' 10"	" " " " " " Tools have tendency to follow old hole - very hard - 6" in 12 hours. Gas in bailer.
1932 May	3	1770'	Shooting to break up boulder which is giving trouble by causing bore to go crooked.
		1812 1	Steeply pitched formation - good gas pressure - cuttings show rich traces of oil.
Sept.	5	( 1902 '3" - ( 1926 '9"	Cuttings showed oil and gas - wet gas for first time in history of field.
	12	1963*	Fishing and splicing rope.
